Fig. 1: Wedge part of an altar crown suspension (after Hadzic 2008, 2),

## ✧ Description and visual observation

Description of the artefact	Construction element used for suspension of an altar crown (Fig. 1) covered with a thin orange-brown corrosion layer.
Type of artefact	Supporting structure
Origin	Abbey of Rheinau, Zürich, Zurich, Switzerland
Recovering date	1720 AD
Chronology category	Modern Times
chronology tpq	1720 A.D. ▼
chronology taq	----- ▼
Chronology comment	
Burial conditions / environment	Indoor atmosphere
Artefact location	Abbey of Rheinau, Zürich, Zurich
Owner	Canton of Zurich, Zurich
Inv. number	None
Recorded conservation data	Not conserved (machine brushed)

## Complementary information

Fig. 3: Micrograph of the cross-section of the sample taken from the wedge part showing the location of Figs. 4 to 12. Steel areas are delimited by black dotted lines,

Description of sample

This sample is a section from the end of the wedge part (Fig. 2). The corrosion crust appears on the top side on Fig. 3.

Alloy

P-rich iron and hypoeutectoid steel

Technology

Annealed after (hot) rolling

Lab number of sample

RHE1-NR

Sample location

Haute École Arc Neuchâtel, Neuchâtel

Responsible institution

IWT (Naila Hadzic), Wallisellen, Zurich

Date and aim of sampling

January 2008, material testing and security report

Complementary information

None.

Analyses and results

Analyses performed:

Metallography (nital etched and etched with Oberhoffer's reagent), Vickers hardness testing, LA-ICP-MS, SEM/EDS.

Non invasive analysis

None.

Metal

The remaining metal (M1) is a P-rich iron (0.3-0.45 mass%) with two zones (M3) consisting of soft, hypoeutectoid steel (C content 0.2 mass%) (Fig. 3 and Table 1). The P-rich iron contains many elongated slag inclusions of various sizes forming parallel rows (Figs. 3 and 4). The number of slag inclusions is higher than in bloomery iron and their distribution is typical for rolled metal. A crack, partially filled by hammer scale and corrosion products, indicates a poor quality welding seam (Fig. 3). Below the inclusions the curve produced by forging is highlighted. In good quality wrought iron slag inclusions are small, uniformly distributed and have identical compositions (Boesenberg 2006, 622). This is not the case in this sample, but can be explained by the rudimentary rolling process of the 18<sup>th</sup> century. The chemical composition of the slag inclusions shows that iron oxides dominate, beside phosphorus oxide, calcium oxide and silica (Table 2). The composition is typical for slag formed by hearth refining of pig iron (Dillmann and L'Héritier 2007). During this process, the pig iron is oxidised. The oxidising elements are Si, P, Mn, V and Cr. The analyzed slag inclusions contain more Fe than most published ones. The high P content is similar to published examples from the 18<sup>th</sup> century (Dillmann and L'Héritier 2007, 1820). The high calcium oxide content, which is often combined with high silica content, could originate from the addition of both materials while refining the pig iron to better eliminate the P. In one of our measurements, only the silica concentration is high (Table 2). This can be interpreted as resulting from the addition of sand during forging. Etching with Oberhoffer's reagent outlines the thick welding seam (M2, Fig. 5), the rolling direction and the P segregation. Etching with nital mainly shows a ferritic structure (Fig. 6). The grains vary in size (between ASTM grain sizes of 4 to 8) and are recrystallized. The ferrite shows local ghost structures, and includes Neumann bands and some needles (Figs. 7 and 8). These are typical structures of P-rich iron. The ghost structure is formed by a fast recrystallization of P-rich iron after heating above 1000°C. The Neumann bands indicate cold working. The hypoeutectoid steel consists of ferrite with lamellar pearlite (Fig. 9). The average hardness of the metal is HV1 185 (in the Empa test report a mean of HV10 175 was determined). The areas close to the welding seam are harder (ca. HV1 210). The calculated tensile strength based on HV1 175 is about 544N/mm<sup>2</sup>.

Corrosion layers

The corrosion crust is thin and irregular. It is restricted to one of the three surfaces. In bright field, the corrosion layer seems homogeneous and appears medium-grey with a fissure parallel to the metal surface (Fig. 10). Under polarised light the corrosion products near the metal surface are mostly red-orange (CP3), whereas in the outer layer they appear orange-brown (CP1) (Fig. 11). A dark-brown zone is visible between them (CP2) and contains bright inclusions with a chemical composition similar to wüstite (Table 3). This corresponds to corroded slag inclusions (internal markers). Chemical analysis (Table 3) and elemental mapping (Fig. 12) do not highlight a difference in composition of the corrosion layers, except for the corroded slag inclusions.

Elements	O	S	Fe	Total
Inner part, dark-brown corrosion layer (CP2)	34	<	61	96
Inner part, orange corrosion products (average of 2 similar analyses) (CP3)	34	<	64	99
Bright inclusion	23		83	106
Middle, orange corrosion products	36	<1	64	101
Outer orange corrosion layer (average of 3 similar analyses) (CP1)	34	<1	62	97

Table 3: Chemical composition (mass %, <: below the detection limit) of the corrosion crust (from Fig. 12). Method of analysis: SEM/EDS, Laboratory of Analytical Chemistry, Empa.

Fig. 10: Micrograph showing the metal - corrosion layer interface from Fig. 3 (reversed picture, detail), unetched, bright field. The grey corrosion layer contains bright inclusion rows. The area selected for elemental chemical distribution (Fig. 12) is marked by the red rectangle which extends beyond the micrograph,

Fig. 11: Micrograph (same as Fig. 10) corresponding to the stratigraphy of Fig. 13, unetched, polarised light. We observe from bottom to top: a red-orange inner corrosion layer (CP3), followed by a dark-brown intermediate layer (CP2) and an orange-brown outer layer (CP1),

Fig. 12: SEM image, BSE-mode, and elemental chemical distribution of the selected area from Fig. 10 (inversed, detail). Method of examination: SEM/EDS, Laboratory of Analytical Chemistry, Empa,
