▼ Description and visual observation

Description of the artefactMetal piece probably coming from a wooden box forming a "L" shape, coverered with iron

corrosion products. Dimensions: L around 10cm and W around 5cm.

Type of artefact Furniture element

Origin Las Cravieros, Fanjeaux, France

Recovering date 2022

Chronology category Early medieval times

chronology tpq 400 A.D. ✓

chronology taq 525 A.D. ✓

Chronology comment

Burial conditions / environment

Soil

Artefact location Las Cravieros, Fanjeaux (Favennec Benoît), Languedoc-Roussillon

Owner None

Inv. number FS665 US10011

Recorded conservation data

Mechanical removal of the corrosion products and protection with resin paraloid B72 in

acetone.

Complementary information

The artefact might have been exposed to high temperatures because it was found around a forging work area.

Credit Materia Viva, C.Moreau.

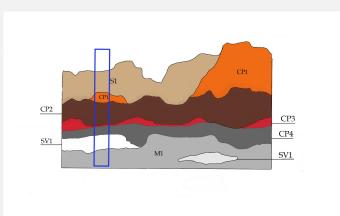

Fig. 5: The blue square indicates the location of the analysed area by binocular observation,

➢ Binocular observation and representation of the corrosion structure

The schematic representation below gives an overview of the corrosion structure(s) encountered on the object from a first visual macroscopic observation.

S1	Sediment	powdery and non adherent
CP1	Corrosion product	bright orange corrosion product or soil orange-coloured by corrosion products
CP2	Corrosion product	brown layer of corrosion products with silica grains
CP3	Corrosion product	very thin discontinuous layer of a red corrosion product without silica grains
CP4	Corrosion product	grey/blue continuous layer
SV1	Structural void	
M1	Metal	compact metal. Observation of stretched metal around the structural voids

Table 1: Description of the principal characteristics of the strata as observed under binocular and described according to Bertholon's method.

∀ MiCorr stratigraphy(ies) – CS		
None.		

♥ Conclusion

This ferrous alloy object that may have belonged to a wooden box was found near a forge area. Among the observed corrosion strata and characteristic of the corrosion process of ferrous metals, two corrosion layers CP3 and CP4 appear atypical compared to other corrosion profiles of similar metals (cf MiCorr | Knife with a groove on both sides DEV 995/814 PR - Fe Alloy - Early medieval times - Switzerland). They could be related to high temperature exposure due to the proximity of a forging zone.

The limit of the original surface is probably between CP2/CP3 and CP3/CP4. Layer CP3 (in red) shows no more silica grain coming from the burial environnement. CP3 can be removed, but this will eliminate certain elements relating to the history of the artefact.
