Fig. 1: Sacrificial knife,

Credit HE-Arc CR, M.Billot.

### ▼ Description and visual observation

**Description of the artefact**Sacrificial knife (tumi) covered with green corrosion products and sediments. Semi circular

flattened cutting edge. Trapezoidal handle with rectangular section. L = 105 mm; W handle =

25 mm; W blade = 55 mm; T = 1 mm; WT = 18,7 g.

Type of artefact Sacrificial knife (tumi in vernacular language)

Origin Cajabamba, Cajamarca, Peru

Recovering date Unknown

Chronology category Unknown

chronology tpq 200 A.D. •

chronology taq 1300 A.D.

Chronology comment None

Burial conditions / environment

Soil

Artefact location Museum der Kulturen, Basel

**Owner** Museum der Kulturen, Basel

Inv. number IVc 24745

Recorded conservation data N/A

### **Complementary information**

Little information on the origin of the artifact. Most likely not documented before being donated to the museum.

Stratigraphic representation of the corrosion structure of the knife (combination of corrosion structures 1 and 2 of Fig. 5) observed macroscopically under binocular microscope using the MiCorr application. The characteristics of the strata are only accessible by clicking on the drawing that redirects you to the search tool by stratigraphy representation, Credit HE-Arc CR, M.Billot.

### 

Description of sample Invasive sampling was not authorized by the museum. Only one powder sample was taken of

the green corrosion product (Fig. 4).

Alloy Cu Alloy

**Technology** Cold worked (laminated)

Lab number of sample 1

Sample location HE-Arc CR, Neuchâtel, Neuchâtel

**Responsible institution** HE-Arc CR, Neuchâtel, Neuchâtel

Date and aim of sampling 02.04.2017, chemical and structural analyses

### Complementary information

None.

### ★ Analyses and results

### Analyses performed:

X-ray radiography\*, XRF\*\*, SEM-EDS, and XRD. Conditions of the XRD analysis: Stoe Mark II-Imaging Plate Diffractometer System (Stoe & Cie, 2015) equipped with a graphite-monochromator. Data collection was performed using Mo-K $\alpha$  radiation ( $\lambda$  = 0.71073Å, beam diameter 0.5mm). Two-dimensional diffraction images (10min. per exposure) were obtained at an image plate distance of 200mm with a continued sample rotation. The resolution was Dmin - Dmax 24.00 - 1.04Å and intensity integration has been performed over the entire image (360°).

<sup>\*</sup> The conditions are unknown.

<sup>\*\*</sup> On the object with handheld X-ray fluorescence spectrometer (NITON XL3t 950 Air GOLDD+ analyser, Thermo Fischer®. Mining mode Cu/Zn, acquisition time 180s (filters: M30/Lo30/H60/Li60)

### ▼ Non invasive analysis

The metal is an arsenical copper alloy with low concentration of iron and traces of silver (Table 1). XRF analyses have been conducted on eight areas, on the two sides of the non-cleaned artefact. Almost all analyses are the same except for the area "5" where a slightly higher concentration of arsenic was measured.

Elements mass%	Cu	As	Ag	Fe	Cl	Al	Si	K	Р	Ca	S	BAL
1	62	<1	<1	<1	<1	4	13	<1	<1	1	<1	18
2	51	<1	<1	<1	<1	1	12	<1	<1	1	<1	32
3	51	<1	<1	<1	<1	3	14	1	<1	1	<1	28
4	53	<1	<1	<1	<1	3	17	1	<1	1	<1	25
5	40	1	<1	<1	2	3	14	1	<1	1	<1	37
6	53	<1	<1	<1	<1	2	12	<1	<1	2	<1	30
7	53	<1	<1	<1	<1	2	12	<1	<1	2	<1	30
8	38	<1	<1	1	<1	3	17	1	<1	1	<1	39

Table 1: Chemical composition of the non-cleaned metal surface. BAL corresponds to the elements not analysed: 0 and C. Method of analysis: XRF, UR-Arc CR.

### × Metal

As indicated above, the metal of the knife might be an arsenic-copper alloy. Its manufacturing technique is not known but the X-radiography image seems to indicate that the artefact might have been produced as-cast with internal flaws (Fig. 7). The object has still a lot of remaining metal. Irregularities and different thicknesses are visible and parallel lines show that the knife was hammered. The whiter the area, the thicker the metal is.

Credit Centre d'Imagerie Médicale, La-Chaux-de-Fonds.

Fig. 7: X-ray radiography of the knife. The base of the blade is thicker and is probably as-cast (red arrow). The blue arrows indicate casting flaws or localized corrosion,

Microstructure Unknown

First metal element Cu

Other metal elements As

### Complementary information

None.

### ▼ Corrosion layers

Results from XRF analyses of the non-cleaned metal surface (Table 1) indicate the presence of chlorine. The exogenous elements come from the landfill are mainly Si and Al, certainly associated to aluminosilicates. A sample was taken in the powdered light-green isolated layer (Figs. 2, 4 and 5). Chlorine, copper and oxygen was analysed by EDS-SEM. The presence of a high amount of Cl as well as Cu and O seems to indicate active corrosion (Fig. 8). XRD analysis confirmed the presence of paratacamite often associated to active corrosion (Fig. 9).

Fig. 10: Improved stratigraphic representation of the tumi from visual observations and analyses,

### ♥ Conclusion

This tumi is an arsenic copper alloy with a low percentage of iron, as well as traces of silver. This alloy was common in pre-Columbian South America (Pillsbury 2001). The X-ray radiography shows that this object was formed from a metal sheet and cold hammered.

Chlorine is found locally in the form of paratacamite.

The limit of the original surface has been altered by the corrosion products but can be found at the interface of CP6 and CP7. This tumi follows the type II corrosion model of L. Robbiola.
