Fig. 1: Leaded bronze tang fragment (after Rychner-Faraggi 1983, plate 35.26),

## ∨ Description and visual observation

<b>Description of the artefact</b>	Tang fragment with shiny brown patina typical of lake context. Dimensions: L = 2.9cm; Ømax. = 6.8mm; WT = 4.9g.
<b>Type of artefact</b>	Knife
<b>Origin</b>	Hauterive - Champréveyres, Neuchâtel, Neuchâtel, Switzerland
<b>Recovering date</b>	Excavation in 1983-1985, layer 3
<b>Chronology category</b>	Late Bronze Age
<b>chronology tpq</b>	<input type="text" value="1054"/> B.C. ∨
<b>chronology taq</b>	<input type="text" value="1000"/> B.C. ∨
<b>Chronology comment</b>	Hallstatt B1 (1054/1037BC_ 1000BC)
<b>Burial conditions / environment</b>	Lake
<b>Artefact location</b>	Laténium, Neuchâtel, Neuchâtel
<b>Owner</b>	Laténium, Neuchâtel, Neuchâtel
<b>Inv. number</b>	Hr 6567
<b>Recorded conservation data</b>	Not conserved

## ∨ Study area(s)

Fig. 2: Location of sampling area,

Binocular observation and representation of the corrosion structure

Stratigraphic representation: none

Sample(s)

Fig. 3: Micrograph of the cross-section showing the locations of Figures 4 to 9,

<b>Description of sample</b>	This cross-section shows a lateral cut through the tang (Fig. 2). Most of the corrosion crust is absent.
<b>Alloy</b>	Leaded Bronze
<b>Technology</b>	Cold worked after annealing
<b>Lab number of sample</b>	MAH 87-196
<b>Sample location</b>	Musées d'art et d'histoire, Genève, Geneva
<b>Responsible institution</b>	Musées d'art et d'histoire, Genève, Geneva
<b>Date and aim of sampling</b>	1987, metallography and corrosion characterisation

Analyses and results

**Analyses performed:**

Metallography (etched with ferric chloride reagent), Vickers hardness testing, ICP-OES, SEM/EDX, XRD.

Non invasive analysis

Metal

The remaining metal is a leaded bronze (Table 1) containing numerous copper sulphide and tiny Pb inclusions (Figs. 4-6, 9 and Table 2). The porosity within the metal is high, particularly along a band through the middle of the sample (Figs. 3 and 4). The etched structure of the leaded bronze shows small, regular polygonal grains, some with twinning (Fig. 5). Strain lines appear in grains close to the metal surface (Fig. 6). The average hardness of the metal is HV1 120.

Elements	Cu	Sn	Pb	Ni	Sb	As	Co	Ag	Fe	Zn
mass%	87.52	8.02	1.46	1.04	0.81	0.60	0.24	0.21	0.05	0.03

Table 1: Chemical composition of the metal. Method of analysis: ICP-OES, Laboratory of Analytical Chemistry, Empa.

Elements	O	S	Fe	Cu	Total

<b>Microstructure</b>	Polygonal and twinned grains + strain lines (metal surface) with pores
<b>First metal element</b>	Cu
<b>Other metal elements</b>	Ni, Sn, Pb

∨ Corrosion layers

The metal has lost most of its original corrosion crust, the remainder having an average thickness between 60 and 190µm (Fig. 3). In some areas up to three corrosion layers are visible (Fig. 7). In polarised light (Fig. 8), the corrosion stratigraphy appears more clearly: it is composed of a dense black inner layer, an intermediate thick brown layer with bright spots (indicating porosity) and an outer red layer with white particles. The elemental chemical distribution of the SEM image reveals that the black inner layer is Sn-rich but contains Cu, O, Ca, S and Fe (Table 3, Fig. 9). The brown layer contains S, Fe, and Cu and has a composition similar to chalcocite/Cu<sub>2</sub>FeS<sub>2</sub> (Table 3, Fig. 9). The red layer is an iron oxide (main elements Fe and O) and is contaminated with calcite/CaCO<sub>3</sub> particles (Table 3, Fig. 9). XRD analyses of the brown layer by Schweizer confirms the presence of chalcocite (1994, museum report (1987)).

Elements	O	Fe	Ni	Cu	Si	P	S	Ca	As	Sn	Pb	Total
CP1e, red layer	37	51	1.8	<	<	<	<	1.5	0.8	<	<	93
CP2i, brown layer	<	30	<	42	<	<	35	<	<	<	<	107
CP2i, white particles	50	<	<	0.6	<	<	<	39	<	<	<	90

CP3i, black layer	39	4.8	1.2	5.2	3.9	3.7	<	<	0.7	37	3.7	100

Corrosion form	Uniform - pitting
Corrosion type	Type I (Robbiola)

✚ MiCorr stratigraphy(ies) – CS

Fig. 4: Stratigraphic representation of the object in cross-section using the MiCorr application. This representation can be compared to Fig. 9.

✚ Synthesis of the binocular / cross-section examination of the corrosion structure

Corrected stratigraphic representation: none

✚ Conclusion

The tang fragment is made from a leaded bronze and has been cold worked on the top surface after annealing. The SEM/EDX examination and past XRD analyses indicate the presence of chalcopryite in the corrosion crust, typical of lake context (Schweizer 1994), enriched with Sn close to the metal surface and depleted of Cu on the outer surface. This object was certainly abandoned rather quickly in an anaerobic, humid and S and Fe-rich environment, favouring then the formation of chalcopryite. The limit of the original surface most probably lies between the Sn-rich inner layer and the Fe and S-rich outer layers. The presence of iron oxides on top of the copper corrosion crust has not yet been explained. The corrosion is a type 1 according Robbiola et al. 1998.
