

BLADE FRAGMENT OF A WINGED AXE FK43 – TIN BRONZE – MIDDLE BRONZE AGE – SWITZERLAND

Artefact name Blade fragment of a winged axe FK43

Authors Marianne. Senn (EMPA, Dübendorf, Zurich, Switzerland) & Christian. Degrigny (HE-Arc CR, Neuchâtel, Neuchâtel,

Switzerland)

▼ The object

Fig. 1: Tin bronze tool fragment. The drilling on the right picture was carried out at a later stage and does not form part of the original object,

➤ Description and visual observation

Description of the artefactBlade fragment of a semi-finished median-winged axe. Its surface is covered with a thick dark green

corrosion crust (Fig. 1). Dimensions: L = 20mm; Tmax. = 8.5mm; WT = 15g.

Type of artefact Tool

Origin Obstgartenstrasse, Erlenbach, Zurich, Switzerland

Recovering date Excavation 1980.002

Chronology category Middle Bronze Age

chronology tpq 1550 B.C. ▶

chronology taq 1350 B.C. ▶

Chronology comment 1550BC _ 1350BC

Burial conditions / environment Soil

Artefact location Kantonsarchäologie, Dübendorf, Zurich

Owner Kantonsarchäologie, Dübendorf, Zurich

Inv. number FK43

Recorded conservation data Not conserved

Complementary information

Nothing to report.

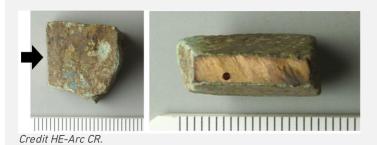

Fig. 2: Location of sampling area (arrow, left picture) and side view (right picture),

Stratigraphic representation: none.

★ MiCorr stratigraphy(ies) – Bi

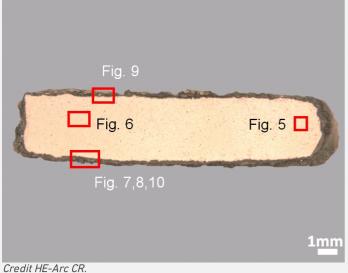

Fig. 3: Micrograph of the cross-section showing the location of Figs. 5 to 10,

Description of sample The sample was cut from the fragment shown in Fig. 2. The cross-section is rectangular in shape (L =

17mm, W= 4mm) and has a thick corrosion crust (Figs. 2 and 3).

Alloy Tin Bronze

Technology As-cast

ERL-43 Lab number of sample

Sample location Begbroke Science Park (Peter Northover), Yarnton, England

Responsible institution Kantonsarchäologie, Dübendorf, Zurich

Date and aim of sampling Date unknown, metallography and chemical analyses

Complementary information

Nothing to report.

★ Analyses and results

Analyses performed:

Metallography (etched with ferric chloride reagent), Vickers hardness testing, SEM/EDS, EPMA/WDS, Raman spectroscopy.

▼ Non invasive analysis

Metal

The remaining metal is a tin bronze (Table 1) with high porosity and grey copper sulphide inclusions (Figs. 5 and 6, Table 2). The etched metal has the typical dendritic structure of a cast tin bronze with an average hardness of HV1 135 (Fig. 6). The cored dendritic structure is surrounded by an alpha-delta eutectoid. The core of the dendrites is rich in Cu whereas the outer layers are rich in Sn.

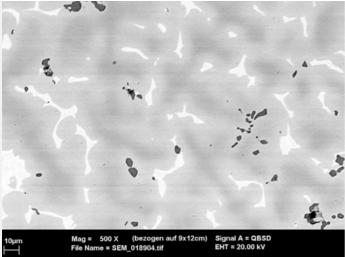

Elements	Cu	Sn	As	Fe	Ni	Pb	Sb	Со	Ag	Au	Zn		Si	
mass%	85.14	11.95	1.54	0.49	0.39	0.18	0.14	0.13	0.02	0.02	<	<	n. d.	

Table 1: Chemical composition of the metal. Method of analysis: EPMA/WDS, Lab Department of Materials, University of Oxford.

Elements	Cu		Fe	Total
Dark-grey inclusion	66	24	10	100

Table 2: Chemical composition (mass %) of the dark-grey inclusions seen in Fig. 5. Method of analysis: SEM/EDS, Laboratory of Analytical Chemistry, Empa.

Fig. 5: SEM image of the metal sample from Fig. 3 (detail), BSE-mode. The cored alpha phase of the dendrites appears in grey, becoming lighter towards the periphery (more Sn). The alpha-delta eutectoid appears in white and the copper sulphide inclusions in dark-grey,

▼ Corrosion layers

A dark green corrosion crust with a thickness between 100 and 320 μ m covers the entire surface of the blade fragment (Fig. 7). It retains a metallic ghost structure (Sn-rich eutectoid alpha + delta phase). Under polarized light localized orange and red corrosion products can be seen at the metal - corrosion crust interface (Fig. 8). Interdendritic corrosion and corroded slip lines can be seen in the metal structure and near fissures (Fig. 9). Elemental mapping (Fig. 10) shows that the green layer is Sn-rich (CP1, probably cassiterite, SnO₂) and depleted of Cu, whereas the orange and red corrosion particles are depleted of Sn and rich in Cu (Fig. 10, Table 3). Their Raman spectra indicate that they are mainly composed of cuprite (Fig. 11). The overall corrosion crust contains 0, Si, C and Fe from the environment, while S is concentrated around the cuprite particles (Fig. 10).

Elements	0	Si		Fe	Ni	Cu	As	Sn	Total
Surface CP1	43	0.8	<	6.2	<	16	1	43	111

Middle CP1	42	1.7	0.7	12	<	10	0.7	43	110
Red/orange CP in CP1	41	0.9	<	4.4	<	36	<	22	104
Remnant metal phase	9	0.7	<	5	0.8	34	<	47	97

Table 3: Chemical composition (mass %) of the corrosion crust from Fig. 7. Method of analysis: SEM/EDS, Laboratory of Analytical Chemistry, Empa.

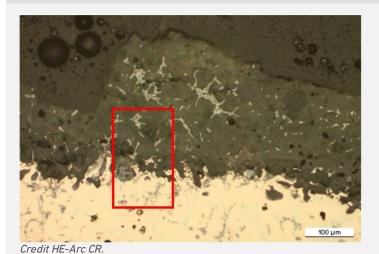

Fig. 7: Micrograph of the metal sample from Fig. 3 (rotated 180°), unetched, bright field. A metallic ghost structure is preserved in the corrosion crust. The mapped area (Fig. 10) is marked by a rectangle,

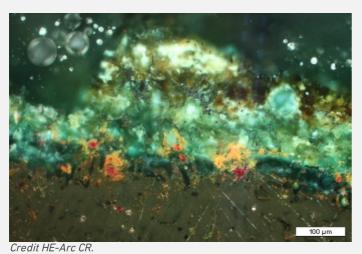

Fig. 8: Micrograph similar to Fig. 7 and corresponding to the stratigraphy of Fig. 4, polarised light. At the metal – green corrosion crust interface red and orange corrosion products can be seen,

imes Synthesis of the binocular / cross-section examination of the corrosion structure

Corrected stratigraphic representation: none.

∀ Conclusion

The evenly corroded tin bronze contains numerous sulphide inclusions and shows signs of interdendritic corrosion penetrating the metal structure. The Sn enriched surface is decuprified and polluted by the environmental elements such as O, Si, Fe, C, Al and Cl. The corrosion crust is composed mainly of a dark green layer with local orange-red cuprite particles at the interface with the remaining metal. Both the remnant metallic phases and the Sn-rich corrosion layer can be interpreted as inferior markers, defining the limit of the original surface which is located above. For the above mentioned reasons, the corrosion is thought to be of type 1 according to Robbiola et al. 1998.
