▼ Description and visual observation

Description of the artefact

Tang fragment with shiny brown patina typical of lake context (Fig.1). Dimensions: L = 2.9cm; Ømax. =

6.8mm; WT = 4.9g.

Type of artefact Knife

Origin Hauterive - Champréveyres, Neuchâtel, Neuchâtel, Switzerland

Recovering date Excavation in 1983-1985, layer 3

Chronology category Late Bronze Age

chronology tpq 1054 B.C. ▶

chronology taq 1000 B.C. ✓

Chronology comment Hallstatt B1 (1054/1037BC _ 1000BC)

Burial conditions / environment Lake

Artefact location Laténium, Neuchâtel, Neuchâtel

Owner Laténium, Neuchâtel, Neuchâtel

Inv. number Hr 6567

Recorded conservation data Not conserved

▼ Binocular observation and representation of the corrosion structure

Stratigraphic representation: none.

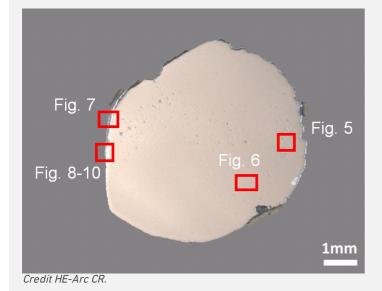

Fig. 3: Micrograph of the cross-section showing the location of Figs. 5 to 10, $\,$

Description of sample

This cross-section shows a lateral cut through the tang (Fig. 2). Most of the corrosion crust is absent (Fig. 3).

Alloy Leaded Bronze

Technology Cold worked after annealing

Lab number of sample MAH 87-196

Sample location Musées d'art et d'histoire, Genève, Geneva

Responsible institution Musées d'art et d'histoire, Genève, Geneva

Date and aim of sampling 1987, metallography and corrosion characterisation

Complementary information

Nothing to report.

Analyses performed:

Metallography (etched with ferric chloride reagent), Vickers hardness testing, ICP-0ES, SEM/EDS, XRD.

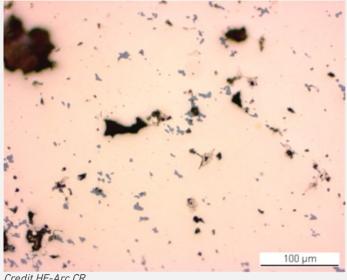

The remaining metal is a leaded bronze (Table 1) containing numerous copper sulphide and tiny Pb inclusions (Figs. 5-7, 10 and Table 2). The porosity within the metal is high, particularly along a band through the middle of the sample (Figs. 3 and 5). The etched structure of the leaded bronze shows small, regular polygonal grains, some with twinning (Fig. 6). Strain lines appear in grains close to the metal surface (Fig. 7). The average hardness of the metal is HV1 120.

Elements	Cu	Sn	Pb	Ni	Sb	As	Со	Ag	Fe	Zn
mass%	87.52	8.02	1.46	1.04	0.81	0.60	0.24	0.21	0.05	0.03

♥ Corrosion layers

The metal has lost most of its original corrosion crust, the remainder having an average thickness between 60 and 190 μ m (Fig. 3). In some areas up to three corrosion layers are visible (Fig. 8). In polarised light (Fig. 9), the corrosion stratigraphy appears more clearly: it is composed of a dense black inner layer, an intermediate thick brown layer with bright spots (indicating porosity) and an outer red layer with white particles. The elemental chemical distribution of the SEM image reveals that the black inner layer (CP3) is Sn-rich, but contains Cu, O, Fe, Si, P, Pb, Ni, As, Ca and S (Table 3, Fig. 10). The brown layer (CP2) contains S, Fe and Cu and has a composition similar to chalcopyrite/CuFeS $_2$ (Table 3, Fig. 10). This was confirmed by past XRD analyses carried out by Schweizer (1994, museum report (1987)). The red layer (CP1) is an iron oxide (main elements Fe and 0) and is contaminated with calcite/CaCO $_3$ particles (Table 3, Fig. 10).

Elements	0	Fe	Ni	Cu	Si		Са	As	Sn	Pb	Total	

CP1, red layer	37	51	1.8	<	<	<	<	1.5	0.8	<	<	93
CP2, brown layer	<	30	<	42	<	<	35	<	<	<	<	107
CP2, white particles	50	<	<	0.6	<	<	<	39	<	<	<	90
CP3, black layer	39	4.8	1.2	5.2	3.9	3.7	<	<	0.7	37	3.7	100

This representation can be compared to Fig. 9, Credit HE-Arc CR.

imes Synthesis of the binocular / cross-section examination of the corrosion structure

Corrected stratigraphic representation: none.

\forall Conclusion

The tang fragment is made from a leaded bronze and has been cold worked on the top surface after annealing. The SEM/EDS examination and past XRD analyses indicate the presence of chalcopyrite in the corrosion crust, typical of lake context (Schweizer 1994), enriched with Sn close to the metal surface and depleted of Cu on the outer surface. This object was certainly abandoned rather quickly in an anaerobic, humid and S and Fe-rich environment, favouring then the formation of chalcopyrite. The limit of the original surface most probably lies between the Sn-rich inner layer and the Fe and S-rich outer layers. The presence of iron oxides on top of the copper corrosion crust has not yet been explained. The corrosion is a type 1 according Robbiola et al. 1998.
