## ≚ Description and visual observation

Description of the artefact   Sacrificial knife. Semi circular flattened cutting edge. Trapezoidal handle with rectangular section. L = 105 mm; W handle = 25 mm; W blade = 55 mm; T = 1 mm; WT = 18,7 g

Type of artefact   Sacrificial knife (tumi in vernacular language)

Origin   Probably Cajamarca (Peru), Cajamarca, Cajamarca, Peru

Recovering date   Unknown

Chronology category   None

chronology tpq | 200 | A.D. ∨ |

chronology taq | 1300 | A.D. ∨ |

Chronology comment   Between 200 at 1300 AD

| Burial conditions / environment	Soil
Artefact location	Museum der Kulturen, Basel
Owner	Museum der Kulturen, Basel
Inv. number	IVc 24745
Recorded conservation data	Not conserved

Complementary information

Little information on the origin of the artifact. Most likely not documented before being donated to the museum.

⩔ Sample(s)

Description of sample	Not applicable since invasive sampling was not authorized by the museum. Only one powder sample was taken of the green corrosion product (Fig. 4).
Alloy	Cu Alloy
Technology	Cold worked (laminated)
Lab number of sample	1
Sample location	HE-Arc CR, Neuchâtel, Neuchâtel
Responsible institution	HE-Arc CR, Neuchâtel, Neuchâtel
Date and aim of sampling	02.04.2017, chemical and structural analyses

Complementary information

Nothing to report.

⩔ Analyses and results

Analyses performed:
X-ray radiography*, XRF**, SEM-EDS, and XRD. Conditions of the XRD analysis: Stoe Mark II-Imaging Plate Diffractometer System (Stoe & Cie, 2015) equipped with a graphite-monochromator. Data collection was performed using Mo-Kα radiation (λ = 0.71073Å, beam diameter 0.5mm). Two-dimensional diffraction images (10min. per exposure) were obtained at an image plate distance of 200mm with a continued sample rotation. The resolution was Dmin - Dmax 24.00 - 1.04Å and intensity integration has been performed over the entire image (360°).

* The conditions are unknown.
** On the object with portable X-ray fluorescence spectrometer (NITON XL3t 950 Air GOLDD+ analyser, Thermo Fischer®).

The metal is an arsenical copper alloy with low concentration of iron and traces of silver (Table 1). XRF analyses have been conducted on eight areas, on the two sides of the non-cleaned artifact. Almost all analyses are the same except for the area "5" where a slightly higher concentration of arsenic was measured.

Elements mass%	Cu	As	Ag	Fe	Cl	Al	Si	K	P	Ca	S	BAL
1	61.9	0.5	0.05	0.4	0.3	3.6	12.6	0.7	0.2	1.1	0.2	18.3
2	51.9	0.3	0.04	0.4	0.3	1.4	11.9	0.7	0.07	0.8	0.1	31.8
3	51.4	0.3	0.04	0.5	0.3	2.5	14.4	0.8	0.1	0.9	0.1	28.2
4	52.7	0.3	0.04	0.5	0.4	2.6	16.6	0.8	0.06	1.1	0.2	24.5
5	39.8	1.1	0.03	0.9	2.2	3.1	13.6	0.8	0.07	1.0	0.4	36.7

Microstructure   None

First metal element   Cu

Other metal elements   As

Complementary information

Complementary information given by X-radiography (Fig. 7) shows that the object is not totally mineralized and still has a lot of remaining metal. Irregularities and different thicknesses are visible and parallel lines show that the knife was hammered. The whiter the area, the thicker the metal is.
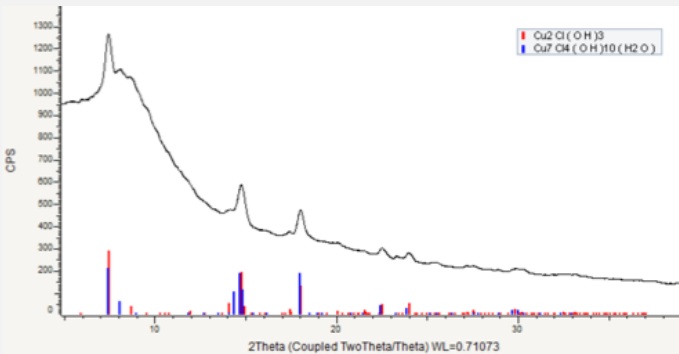

⌄ Corrosion layers

Results from XRF analyses of the non-cleaned metal surface (Table 1) indicate a high concentration of chlorine. The exogenous elements come from the landfill are mainly Si and Al, certainly associated to aluminosilicates. A sample was taken in the powdered light-green isolated layer (Figs. 2, 4 and 5). Chlorine, copper and oxygen was analysed by EDS.SEM. The presence of a high amount of Cl as well as Cu and O seems to indicate active corrosion (Fig. 8). XRD analysis confirmed the presence of paratacamite often associated to active corrosion (Fig. 9).

⌄ MiCorr stratigraphy(ies) – CS

⌄ Synthesis of the binocular / cross-section examination of the corrosion structure

The schematic representation of corrosion layers of Fig. 5 integrating additional information based on the analyses carried out is given in Fig. 10. The limit of the original surface (represented by the dotted line on the figure below) was identified as still present and is located at the interface between CP6 and CP7.
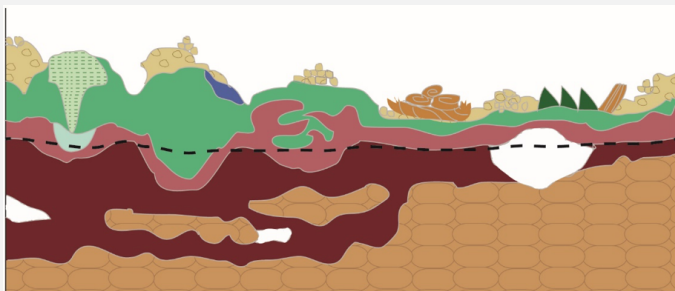

Fig. 10: Improved stratigraphic representation of the tumi from visual observations and analyses,

	Name	Aspect	Composition
	S1	Soil (sand and limestone)	Si, O, C, Al,K, P, Ca, S (Al$_2$O$_3$, SiO, etc.)
	POM1	Textile and plant fibers	
	CP1	Small dark-green crystals	Unknown, maybe paratacamite Cu$_2$Cl(OH)$_3$?
	CP2	Green layer	Unknown, probably malachite Cu$_2$CO$_3$(OH)$_2$
	CP3	Occasional powdery light-green layer	Paratacamite Cu$_2$Cl(OH)$_3$ and hydrated hydroxychloride Cu$_7$Cl$_4$(OH)$_{10}$ (H$_2$O)
	CP4	Light-blue ponctual layer	Unknown, probably nantokite CuCl
	CP5	Scarce blue layer	Unknown, probably azurite Cu$_2$CO$_3$(OH)$_2$
	CP6	Light-red layer	Unknown, probably cuprite CuO
	CP7	Dark red-layer	Unknown, probably cuprite CuO
	M1	Metal	Probably Cu with low percent of As and Fe. Trace of Ag.
	SV	Structural void	——

Credit HE-Arc CR, M.Billot.

⌄ Conclusion

This tumi is an arsenic copper alloy with a low percentage of iron, as well as traces of silver. This alloy was common in pre-Columbian South America (Pillsbury 2001). The X-ray radiography shows that this object was formed from a metal sheet and cold hammered.
Chlorine is found locally in the form of paratacamite.
The limit of the original surface has been altered by the corrosion products but can be found at the interface of CP6 and CP7. This tumi follows the type II corrosion model of L. Robbiola.
