Fig. 1: Oenochoe, belly / neck of the vessel with its base. Only the base is considered in the present file,

## ≡ Description and visual observation

<b>Description of the artefact</b>	Base of an oenochoe (Fig. 1) developing locally green corrosion products covered or not with sediments. Dimensions: L = 82 mm; W = 74 (after degradation) ; T = 6,5 mm; WT = 30,9 g.
<b>Type of artefact</b>	Oenochoe, vessel
<b>Origin</b>	Place Simon-Goulart, Genève, Geneva, Switzerland
<b>Recovering date</b>	Excavation 2012
<b>Chronology category</b>	Roman Times
<b>chronology tpq</b>	20 B.C. ▼
<b>chronology taq</b>	50 A.D. ▼
<b>Chronology comment</b>	
<b>Burial conditions / environment</b>	Soil
<b>Artefact location</b>	Service cantonal d'archéologie, Genève, Geneva
<b>Owner</b>	Service cantonal d'archéologie, Genève, Geneva
<b>Inv. number</b>	GV132-01/US26-obj.10
<b>Recorded conservation data</b>	Not conserved

<b>Description of sample</b>	The sample was cut from the edge shown in Fig. 2. Its dimensions are L = 6.5 mm, W = 1.5 mm. The sample contains some remaining metal covered with a crust and a voluminous pustule corrosion (Fig. 4).
<b>Alloy</b>	Tin Bronze
<b>Technology</b>	Cold worked with repeated annealing and final cold working
<b>Lab number of sample</b>	HECR 1455 – S2
<b>Sample location</b>	HE-Arc CR, Neuchâtel, Neuchâtel
<b>Responsible institution</b>	Musée cantonal d'archéologie et d'histoire, Lausanne, Vaud
<b>Date and aim of sampling</b>	2013, metallography and chemical analyses

## Analyses and results

<p><b>Analyses performed:</b> Metallography (etched with ferric chloride reagent), SEM-EDS.</p>
---

## Non invasive analysis

--

## Metal

The remaining metal is a tin bronze (Table 1). The etched metal shows a structure of polygonal grains with twinned and strain lines (Fig. 8).

Elements	Cu	Sn
mass%	91	9

Table 1: Chemical composition of the metal. Method of analysis: SEM-EDS, Lab of Electronic Microscopy and Microanalysis, IMA (Néode), HEI Arc.

Fig. 7: SEM image of the metal sample from Fig.4 (rotated 30°), BSE-mode,

Fig. 8: Micrograph of the metal sample from Fig. 4, etched, bright field, 50x. Polygonal and twinned grains with strain lines are observed. The dotted surface is the result of over-etching,

Microstructure	Polygonal grains with twinned and strain lines
First metal element	Cu
Other metal elements	Sn

Complementary information

Corrosion layers

Intergranular corrosion is observed on the edges of the remaining metal (Fig. 9).The sample shows two forms of corrosion: multi-layered pustule corrosion at the left extremity of the sample (Fig. 10, area 1) and a corrosion crust covering the metal (Fig.10, area 2). The multi-layered pustule corrosion has an average thickness of about 1.1 mm (L) and 0.79 mm (W) (Fig.11). It is composed of a sandwich of 7 corrosion products, mainly green, grey, red and blue in dark field. Microscopic observation allows us to highlight new corrosion products that were not detected during the first visual examination (Fig. 11):

CP1. Light grey layer, containing mainly Sn, O, some Fe, P and a small amount of Pb combined with dark green layer, containing mainly Cu, O and P (Fig. 12, Fig. 5 and table 2)

CP2. Blue layer, containing mainly Cu, Cl (Fig. 12, Fig. 5 and table 2)

CP3. Red layer, containing mainly Cu and O combined with black layer containing mainly Sn and O (Fig. 12, Fig. 5 and table 2)

CP4. Brown layer containing mainly Cu, Sn and O (Fig. 12, Fig. 5 and table 2)

CP5. Dark grey layer containing mainly Cu, Sn and O (Fig. 12, Fig. 5 and table 2)

Superior markers such as contextual Fe and P are present in several layers. Their penetration illustrates the cracking of the primary corrosion layer during the formation of the pustule. The P-enrichment in some corrosion layers may be due to an environment rich in organic material (for example bones). The multi-layered pustule corrosion type has developed similarly to the process presented by Formigli (1975) and Scott (2002).

The corrosion crust on the metal has an average thickness of about 70 µm (Fig. 13). It consists of two sub-layers. The inner corrosion layer (CP2) is thin and dark brown in dark field or light grey in bright field. It has penetrated into the metal structure in some areas (Fig. 9). In dark field, the outer corrosion layer (CP1) is constituted of a heterogeneous light grey corrosion crust (Fig.13). The inner brown corrosion layer is enriched in Sn and O but also contains P, while the outer light grey corrosion layer is mainly composed of Pb and O but also contains P and Fe (Fig. 12). The outer light grey layer is probably due to the presence of a soft solder used to assemble the base to the body.

Elements	Cu	Sn	O	P	Fe	Pb	Cl
Grey layer	nd	+++	++	++	++	+	nd
Dark green layer	++	nd	+++	+++	+	+	+
Blue layer	+++	nd	+	nd	nd	nd	+++
Red layer	+++	nd	++	nd	+	nd	nd
Black layer	nd	+++	+++	+	+	+	nd
Brown layer	++	++	++	nd	nd	nd	nd
Dark grey layer	++	++	++	nd	nd	nd	nd
Light grey layer (crust)	nd	nd	++	+	+	+++	nd
Dark brown layer (crust)	nd	+++	++	+	+	+	nd

Table 2: Chemical composition of the multi-layered pustule corrosion from Figs. 10, 11 and 12 in dark field. SEM-EDS, Lab of Electronic Microscopy and Microanalysis, IMA (Néode) (+++: high concentration, ++ medium concentration, + low concentration, nd: not-detected).

#### ✧ Synthesis of the binocular / cross-section examination of the corrosion structure

The schematic representation of corrosion layers of Fig. 3 integrating additional information based on the analyses carried out is given in Fig. 14. The addition of "e" and "i" within the coding refers to the location of the strata which are either internal ("i") or in contact with the atmosphere ("e").

Fig. 14: Improved stratigraphic representation of the multi-layered pustule form of the oenochoe from visual observations and analyses,

#### ✧ Conclusion

The metal of the oenochoe's base is a tin bronze. The polygonal and twinned grains with strain lines show that the base has been repeatedly cold worked and annealed with a final cold work. The metal is either well preserved or heavily corroded with the formation of pustules that go through the whole thickness of the metal. The limit of the original surface corresponds to the top surface of the dark brown layer. In the presence of a pustule it is highly deformed but discernible by the tin enriched surface. The corrosion is multifactorial. The well preserved and only lightly corroded areas are of Robbiola type 1 (Robbiola 1998), the pustules however are of the Formigli type (Formigli 1975).
