Credit HE-Arc CR, L.Ruynat.

✎ Description and visual observation

| | |
|------------------------------------|--|
| Description of the artefact | The object is the tip of a cooking pot handle representative of the Augustan age (100 AD), recognisable by the axial symmetry and the two orifices surrounded by prominent edging and flared shape. The upper part is composed of an openwork flower with three petals, comparable to the representation of the fleur-de-lis. A curved pattern frieze can be seen in the centre of the object. No decoration was found on the back. Before treatment, the object was covered with green corrosion products and organic remains, most of which were mineralised (Figs. 1a and b). Dimensions : L = 73 mm ; W = 48 ; T = 9 mm ; WT = 80.8 g. |
| Type of artefact | Household implement |
| Origin | Romans legionnaires' camp of Vindonissa (present-day town of Windisch), Aargau canton, CH., Windisch, Aargau, Switzerland |
| Recovering date | 2008 |
| Chronology category | Roman Times |
| chronology tpq | 1 A.D. ▼ |
| chronology taq | 100 A.D. ▼ |
| Chronology comment | 1st century AD |

| Owner | Archaeological Service of the Aargau canton, Brugg, Aargau |
| Inv. number | V.008.2/2948.1. (Inv. Number at HE-Arc: 2001) |
| Recorded conservation data | 2008: Probably a first sediment clearing by archaeologists during the excavation. 2016-17: Lucile Ruynat, mechanical removal of the corrosion products over the limits with ultrasonic scalpel. Conservation of wooden remains at the top right of the front of the object. Protective layer (varnish) with acrylic resin Paraloid B72®. |

Complementary information

The soil of Windisch is on the border between calcareous soil (Jura) and molasses-type (Swiss plateau). Calcareous soils tend to be alkaline whereas the molassic soil is generally more neutral. The Swiss climate is temperate, with the four marked seasons. It can have strong frosts in winter.

Study area(s)

Fig. 2: Cooking pot handle after treatment: front (left) and back (right). Location of sampling for SEM-EDS and Raman (red square 1), XRD analyses (red squares 1 and 2), as well as XRF analyses (blue points 3, 4, 5),

Binocular observation and representation of the corrosion structure

The stratigraphy below gives an overview of the corrosion layers encountered on the object from visual macroscopic observation. The stratigraphy was created before treatment by observation under a binocular microscope and modified during the mechanical removal of corrosion products.

✧ MiCorr stratigraphy(ies) – Bi

Fig. 4: Stratigraphic representation of the cooking pot handle fragment under binocular using the MiCorr application (to be compared to Fig. 3). The stratum SV1 is missing because it is integrated in CP2 and it was not possible to represent it in MiCorr while POM1 and POM2 are merged as POM1. The characteristics of the strata are only accessible by clicking on the drawing that redirects you to the search tool by stratigraphy representation, Credit HE-Arc CR, L.Ruynat.

✧ Sample(s)

Description of sample

No sample from the metal was possible. Only a few invasive samples were taken for analysis of corrosion products, as indicated on figure 2 (red squares 1 and 2).

Alloy

Leaded Bronze

Technology

As-cast

Above the well-preserved metal core, CP4 is discontinuously interlocked in CP5. The XRD analysis done on a sample (Fig. 2, red square 2) of both corrosion products, shows that they are mainly constituted of cuprite (Cu_2O), (Fig. 5). The colour difference can be explained by a tin enrichment in the darker CP4, as measured by XRF. XRF analyses of CP4 (Fig. 2, blue dot 5) and CP5 (Fig. 2, blue dot 4) are given in Table 2. The EDS analysis of the light green CP3 (red square 1 Fig. 2) layer did not reveal the presence of chlorides (Fig. 6). Complementary XRD analysis validated the absence of nantokite. Indeed the XRD and Raman indexing was not successful probably because the compound has a large amorphous part. The other layers were not analysed, we expect CP1 and CP2 to be malachite (copper carbonate hydroxyde) because of the green colour and absence of chlorides. Organic remains were mineralised and preserved by the corrosion process.

| Elements mass % | Cu | Sn | Pb | Sb | As | Ag | Fe | P | Cl | S | BAL |
|----------------------|------|------|------|-----|-----|------|------|-----|-----|-----|------|
| Dark-red layer (CP4) | 24.9 | 18.2 | 11.2 | 0.7 | 0.1 | 0.09 | 0.1 | 0.3 | 0.4 | 7.2 | 36.1 |

✧ Conclusion

The object is a leaded bronze with a well-preserved metal core. Covering the metal are two strata (CP4 and CP5) composed of cuprite, the darker (CP4) appears enriched in tin. The superior interface of these layers represents the limites. In areas the limites, CP4 and CP5 have been replaced by a light green porous corrosion product (CP3). The following layers CP2 and CP1 are probably malachite. The powdery green corrosion layer CP3 has frequently been observed on bronzes of Vindonissa where it can be located within cuprite or malachite layers. It is typically developed below the limites and renders the latter extremely fragile. The nature of this corrosion product has not yet been determined. However, the absence of chlorine indicates that it is not a chlorinated corrosion product such as atacamite or paratacamite. The aggressive urban soil could be a reason for the transformation of these naturally grown and stable corrosion layers.
