Fig. 1: Pin or needle fragment (after Rychner-Faraggi 1993, plate 74.11),

## ∨ Description and visual observation

<b>Description of the artefact</b>	Pin or needle fragment (Fig. 1). The patina is green-blue and granulated, typical of terrestrial context. Dimensions: L = 9cm; Ø = 2.5-2.9mm; WT = 3.6g.
<b>Type of artefact</b>	Pin
<b>Origin</b>	Hauterive - Champréveyres, Neuchâtel, Neuchâtel, Switzerland
<b>Recovering date</b>	Excavation 1983-1985, object from layer 1 (containing material from the Bronze Age until the 20th century)
<b>Chronology category</b>	Late Bronze Age
<b>chronology tpq</b>	<input type="text" value="1050"/> B.C. ▼
<b>chronology taq</b>	<input type="text" value="800"/> B.C. ▼
<b>Chronology comment</b>	Hallstatt A2/B
<b>Burial conditions / environment</b>	Lake
<b>Artefact location</b>	Laténium, Neuchâtel, Neuchâtel
<b>Owner</b>	Laténium, Neuchâtel, Neuchâtel
<b>Inv. number</b>	Hr 3031
<b>Recorded conservation data</b>	Not conserved

## Complementary information

Considered to be a land patina by Schweizer (1994).

Sample(s)

Fig. 4: Micrograph of the cross-section of the sample taken from the pin or needle fragment with green-blue patina showing the location of Figs. 6 to 10,

Credit HE-Arc CR.

<b>Description of sample</b>	The cross-section is circular and is a complete section through the pin (Fig. 2). The surface is completely covered with a rather thin corrosion crust of irregular thickness (Fig. 4).
<b>Alloy</b>	Tin Bronze
<b>Technology</b>	Cold worked after annealing
<b>Lab number of sample</b>	MAH 87-195
<b>Sample location</b>	Musées d'art et d'histoire, Genève, Geneva
<b>Responsible institution</b>	Musées d'art et d'histoire, Genève, Geneva
<b>Date and aim of sampling</b>	1987, metallography and corrosion characterisation

#### Complementary information

This sample is mentioned in Schweizer, 1994.

#### ∨ Analyses and results

##### **Analyses performed:**

Metallography (etched with ferric chloride reagent), Vickers hardness testing, ICP-OES, SEM/EDS, XRD.

#### ∨ Non invasive analysis

#### ∨ Metal

The remaining metal is a tin bronze and contains small copper sulphide and Pb-rich inclusions evenly distributed throughout the metal (Fig. 6, Tables 1 and 2). The Pb-rich inclusions are only visible with SEM appearing as white particles. The etched structure of the tin bronze shows re-crystallised and angular grains, some of them with twins (Fig. 7). Strain or slip lines are visible, especially near the metal surface. They indicate a final cold working. Copper sulphide inclusions are found both at the grain boundaries and inside the grains (Fig. 7). The average hardness of the metal is about HV1 120.

Elements	Cu	Sn	Sb	Ni	As	Pb	Ag	Co	Zn	Fe
mass%	91.29	5.65	1.00	0.69	0.55	0.51	0.22	0.06	0.01	0.02

<b>Microstructure</b>	Polygonal and twinned grains + strain lines (metal surface)
<b>First metal element</b>	Cu
<b>Other metal elements</b>	Ni, As, Ag, Sn, Sb, Pb

#### Complementary information

Schweizer (1994) indicates that the copper-tin alloys similar to the one of the pin have minor constituents that were certainly not added intentionally. Furthermore, he mentions that there is no systematic composition difference between bronzes with a lake patina and those with a land patina.

Corrosion layers

The corrosion crust has an average thickness of about 50µm (Fig. 8). In polarised light (Fig. 9), the corrosion stratigraphy is more clearly visible: it is composed of an inner dark red-green-yellow corrosion layer (CP6 to CP8, an agglomerate of nanoscale stannic oxides with cuprite) directly on the metal core (Table 3 and Fig. 10, already studied by Piccardo et al. 2007), an intermediate multi-layered black-grey bands (CP3 to CP5) and an outer turquoise-green layer (CP1-CP2) analysed with XRD by Schweizer and identified as malachite/CuCO<sub>3</sub>Cu(OH)<sub>2</sub> (Schweizer 1994). In some areas the dark-red layers (CP8) can also be found in between the black-grey bands (CP3 to CP5) and the malachite (CP1-CP2). Elemental chemical distribution of the SEM image of Fig. 10 shows that the black-grey layers are enriched in Sn but also contain Fe. Superior markers such as contextual Al and Si are present in the outer malachite layers. S is present both on the rim of the outer black-grey layers and in the malachite (Fig. 10, Table 3).

Elements	O	Cu	Sn	S	Cl	Fe	As	Ag	Total
CP6	20	40	12	15	<	5	<	1.9	94
CP8	20	53	16	<	0.9	<	0.6	<	91

Fig. 8: Micrograph of the metal sample from Fig. 4 (detail) and corresponding to the stratigraphy of Fig. 5, unetched, bright field. Stratigraphy of the corrosion crust: inner light grey layer (CP3), intermediate dark grey layer with a light-grey rim (CP2) and outer grey-green layer (CP1),

Credit HE-Arc CR.

Fig. 9: Micrograph of the metal sample from Fig. 4 and corresponding to the stratigraphy of Fig. 5, polarised light. The metal appears in brown; the inner layer appears as red-orange, the intermediate layer as black and the outer layer as turquoise,

## ✧ Conclusion

The pin is made from a tin bronze and has been repeatedly cold worked and annealed. After the last annealing there has been some cold work, as can be seen from the strain lines visible after etching the metal. Due to the presence in the corrosion crust of an outer malachite layer, the corrosion was described as terrestrial by Schweizer (Schweizer 1994). The elemental chemical distribution of the corrosion crust shows a more complex situation: as expected for an object buried in a terrestrial site, a typical enrichment of Sn is observed in the inner and intermediate layers covering the remaining metal surface. However it is combined with Fe and S which are often present in lake patinas. According to Schweizer, these layers were formed in anaerobic conditions and developed later on into malachite in an aerated soil through partial dehydration (Schweizer 1994, Schwartz 1934). Since the original surface is absent (destroyed), we refer to type 2 corrosion after Robbiola et al. 1998.
