#### ∨ Analyses and results

##### *Analyses performed:*

Metallography (nital etched after etching with Oberhoffer's reagent), Vickers hardness testing, LA-ICP-MS, SEM/EDS.

#### ∨ Non invasive analysis

#### ∨ Metal

The remaining metal is a Mn-rich soft steel (C content around 0.1 mass%) containing manganese sulphide inclusions with a varying Fe content (Tables 1 and 2). The numerous inclusions form parallel rows (Fig. 5). This orientation is typical for hot rolled metal. After etching with Oberhoffer's reagent, three main welding seams (P-rich) become visible (Fig. 6). Near the surface they are also outlined by corrosion (Figs. 5 and 11). After nital etching, the metal shows a ferritic structure with tertiary cementite and lamellar pearlite at the grain boundaries (Figs. 7 and 8). The grains are small with an ASTM grain size of 10 and are recrystallized due to annealing after hot rolling. The average hardness of the metal is HV1 165. The hardness is slightly high for such a structure and this is due to the Mn content of the metal. The chemical composition, especially the Mn content and the presence of carbo-nitrides (not analysed here), is typical for Thomas steel.

∨ Corrosion layers

The average thickness of the corrosion products is about 80µm (Figs. 5 and 9). In bright field they appear grey, marbled and heavily cracked (Fig. 9). Under polarised light, the corrosion products appear orange to dark-brown (Fig. 10). At the metal - corrosion products interface they are dark-brown (CP3). The middle part (CP2) is red-orange and the outer part is bright orange (CP1). The elemental mapping of the corrosion layers shows no distinctive stratification, but areas near the metal - corrosion crust interface (CP3) as well as the top surface of the corrosion layer (CP1) seem to have a lower O content (Fig. 11). The O content indicates the presence of iron hydroxides (Table 3). Soil materials (such as rock fragments and dust) are found in the welding seams near the surface.

| Location                    | Elements | O  | S   | Mn  | Fe | Total |
|-----------------------------|----------|----|-----|-----|----|-------|
| In welding seam             |          | 34 | <   | <   | 67 | 102   |
| Inner corrosion layer (CP3) |          | 38 | 0.7 | 0.8 | 66 | 106   |

### ∨ MiCorr stratigraphy(ies) – CS

Fig. 4: Stratigraphic representation of the sample taken from the fitting in cross-section (dark field) using the MiCorr application. The characteristics of the strata are only accessible by clicking on the drawing that redirects you to the search tool by stratigraphy representation. This representation showing for the metal part a welding seam (M2) can be compared to Fig. 10, Credit HE-Arc CR.

### ∨ Synthesis of the binocular / cross-section examination of the corrosion structure

Corrected stratigraphic representation: none.

### ∨ Conclusion

The fitting was produced from Mn-containing Thomas steel. It was forged out of four strips, hot rolled and annealed. The corrosion contains only few external markers such as sand grains and dust particles in the outermost layers. The presence of soil materials in the welding seams near the surface could be due either to the corrosion progress (by diffusion through the corrosion crust) or to the manufacturing process.
